Do this in python

First I need to read 3 xlsx files.

Now in the first file there is TRF ID column; and in the second file there is id column so now find TRF ID in id(file 2)(and if not found in file2 than search it in file3 match it with entity_id col) and fetch the settlement_utr value and amount value from the second sheet. Fetch all this in the 4th new file which includes all the columns of file1, settlement_utr col as UTR amount col (from file2 or file 3 which very find) and one more i.e difference of Amount col of sheet1 and amount col of file2(or file3). If settlement_utr is null than set it to 0 in UTR col
